

Injection		
Local anaesthesia	The user injects a small bolus of local anaesthetic and observes the spread of local anaesthetic around the nerve.	
	If the spread is satisfactory, the needle is again aspirated and the preselected amount of local anaesthetic is injected.	
	If the initial spread is unsatisfactory, the needle is repositioned and Step 'Needle to nerve proximity' is repeated.	
Conformance	Once the desired amount of local anaesthetic has been injected and the spread of local anaesthetic has been identified as satisfactory, the needle is removed and the adequacy of the block can be assessed.	
	The patient is continuously monitored for symptoms and signs of local anaesthetic systemic toxicity.
